Rolling resistance measurement on the road: A dream?

Dr. Jürgen Bredenbeck

Tire Technology Expo,
14.-16. February 2012 Cologne

The AND logo, rendered in a bold, blue, sans-serif font.

Content

- Motivation
- Introduction of the used Measurement Equipment
- Introduction of the theoretical approach
- Description of the Test procedure
- Results
- Summary / Conclusions

Motivation

- The demand to higher efficiency concerns each component of future vehicles
- Tire resistance is identified as one of the areas for efficiency improvements independent of vehicle drive concepts
- Understanding the behavior in real road conditions will become more important
- Standard testing methods (drum based) do not deliver road condition related information
- Real road conditions measurement was suffering from:
 - Accurate measurement equipment for the forces as
Tire resistance value is relative low
 - Low repeatability
 - Ability to separate different influence sources

- Motivation
- Introduction of the used Measurement Equipment
- Introduction of the theoretical approach
- Description of the Test procedure
- Results
- Summary / Conclusions

Measurement Equipment on Road

- Vehicle measurement System (VMS)
 - Wheel Force Sensor(WFS)
 - Wheel Position Sensor (WPS)
 - Other sensors such as GPS
 - Vehicle ECU Information

Rig Measurement Equipment

- Flat belt tire testing rig (steel belt)
 - Best simulation of the road
- Test is performed with the same sensor used for the vehicle testing

| Rig Specification | |
|---|---|
| Velocity | 0~200km/h |
| Slip Angle | $\pm 20\text{deg}$ (0~3Hz) |
| Camber Angle | $\pm 15\text{deg}$ (0~1Hz) |
| Up & Down | 0~50mm (0~25Hz) |
| Load | Fx: ± 10 kN Fy: ± 10 kN Fz: 12 kN |
| Flatness of the steel belt (under load condition) | Less than 10 μm |
| Bearing under the belt | Air bearing |

Wheel Force Sensor (WFS)

6 component in wheel force sensor main properties

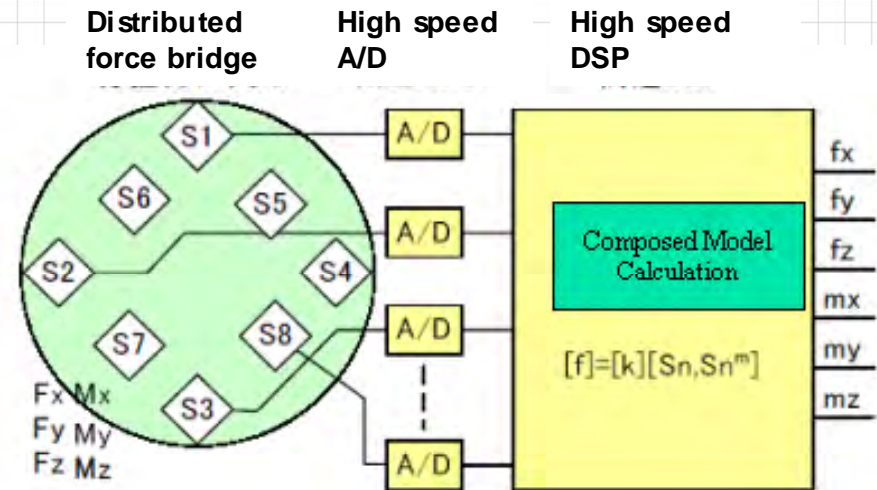

- 3 axis of force and 3 axis of moment
- Total error 0.1%
- Capacity:
 - $F_x = 24\text{KN}$, $F_y = 15\text{KN}$, $F_z = 24\text{KN}$
 - $M_x = 4.5\text{ KNm}$, $M_y = 4\text{ KNm}$,
 $M_z = 4.5\text{KNm}$
- Resolution 1/4000
 - 6N or 1.8Nm
- Data acquisition up to 1kHz
- Lightweight 3.2 Kg

Unique Force Detection Method

- Model Based Sensor concept
 - Shared force detection method
 - Eight bridges are applied to the spring element
 - No direct detection of each component
 - Components are re-composed by model based calculation using real time calculation DSP platform
 - Digital conversion of all signals and electronically re-composing overcomes disadvantages of analogue approach
 - Cross talk error can be canceled out

Minimized Temperature effects

- Vehicle measurement is a challenge for the temperature influence
 - Temperature gradient e.g. break side outside
 - Quick change of temperature depending on driving maneuver
- Need for robust design against Temperature effects
 - Share Force method allows to place the strain gauges very close to each other
 - Total gradient on each gauge is very small
 - Small temperature effect on the measurement
 - At the same time robustness against dynamic temperature changes

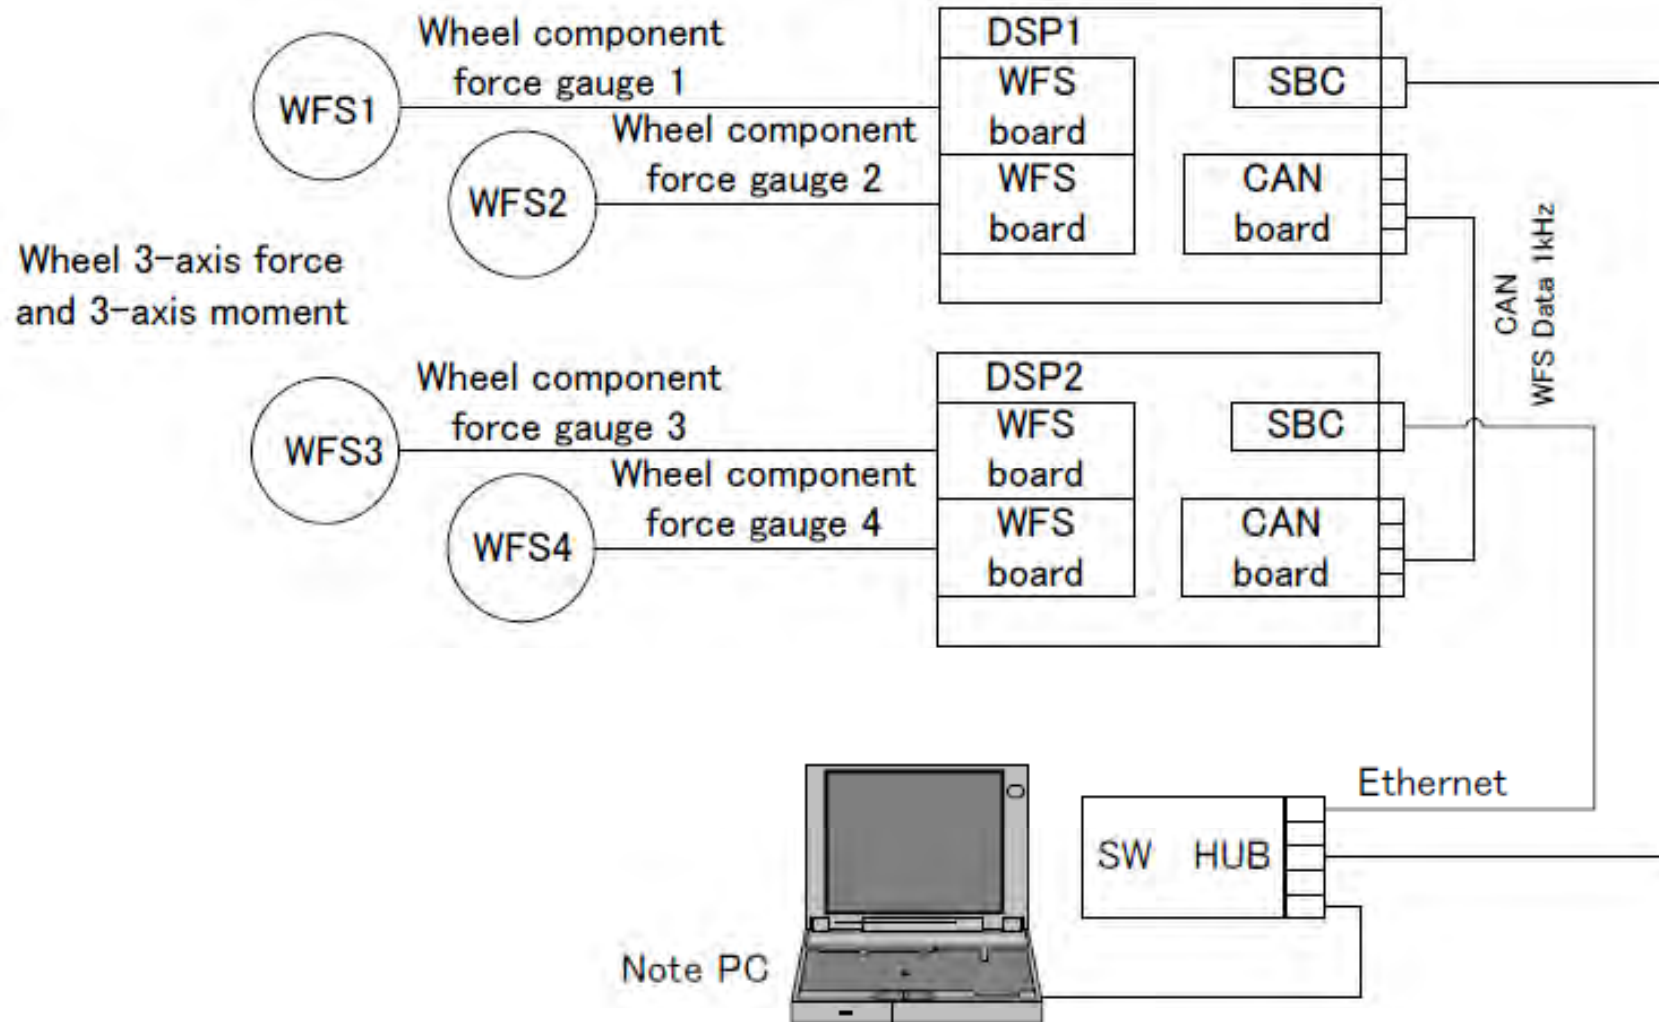

Mechanical and Electrical sensitivity

- Application needs stiff sensor and high accuracy
- Sensor sensitivity:
 - Mechanical sensitivity x electrical sensitivity
- Stiff Spring element design results in:
 - Increase of robustness
 - Increase of eigenfrequency
 - Reduction of mechanical sensitivity
- Increase electrical sensitivity by utilizing:
 - High precision A/D converting of nV order
 - Low noise design from less analog circuit
 - Optimized temperature compensation from gauge layout
- The combination of all technology results in a high accurate sensor with 1/4000 resolution

Wheel Force Sensor Configuration

- Motivation
- Introduction of the used Measurement Equipment
- **Introduction of the theoretical approach**
- Description of the Test procedure
- Results
- Summary / Conclusions

Tire Loss Theory

- Tire loss can be calculated from measured parameters on the wheel
- Measurement parameters
 - Tire rolling inertia J_t in $\text{kg} \cdot \text{m}^2$
 - Tire effective radius r_t in m
 - Wheel torque M_y in Nm
 - Tire longitudinal force F_x in N
 - Tire Angular speed ω in rad/s
 - Tire Angular acceleration $\dot{\omega}$ rad/s²
- Calculated parameter
 - Tire loss (rolling resistance) R_x in N

$$R_x = \frac{M_y + J_t * \dot{\omega}}{r_t} - F_x$$

- Motivation
- Introduction of the used Measurement Equipment
- Introduction of the theoretical approach
- **Description of the Test procedure**
- Results
- Summary / Conclusions

Testing procedure on the test track

- Target: Determine “Tire Loss” from real driving condition
- Test car: BMW Mini Cooper S
- Test Track:
 - Total length: 1,792m
 - East straight line: 550m
 - West straight line: 554m
- Driving Maneuver:
 - Acceleration at west straight line
 - Coast down at East straight line
 - Test laps: 10 laps
- 100Hz data acquisition

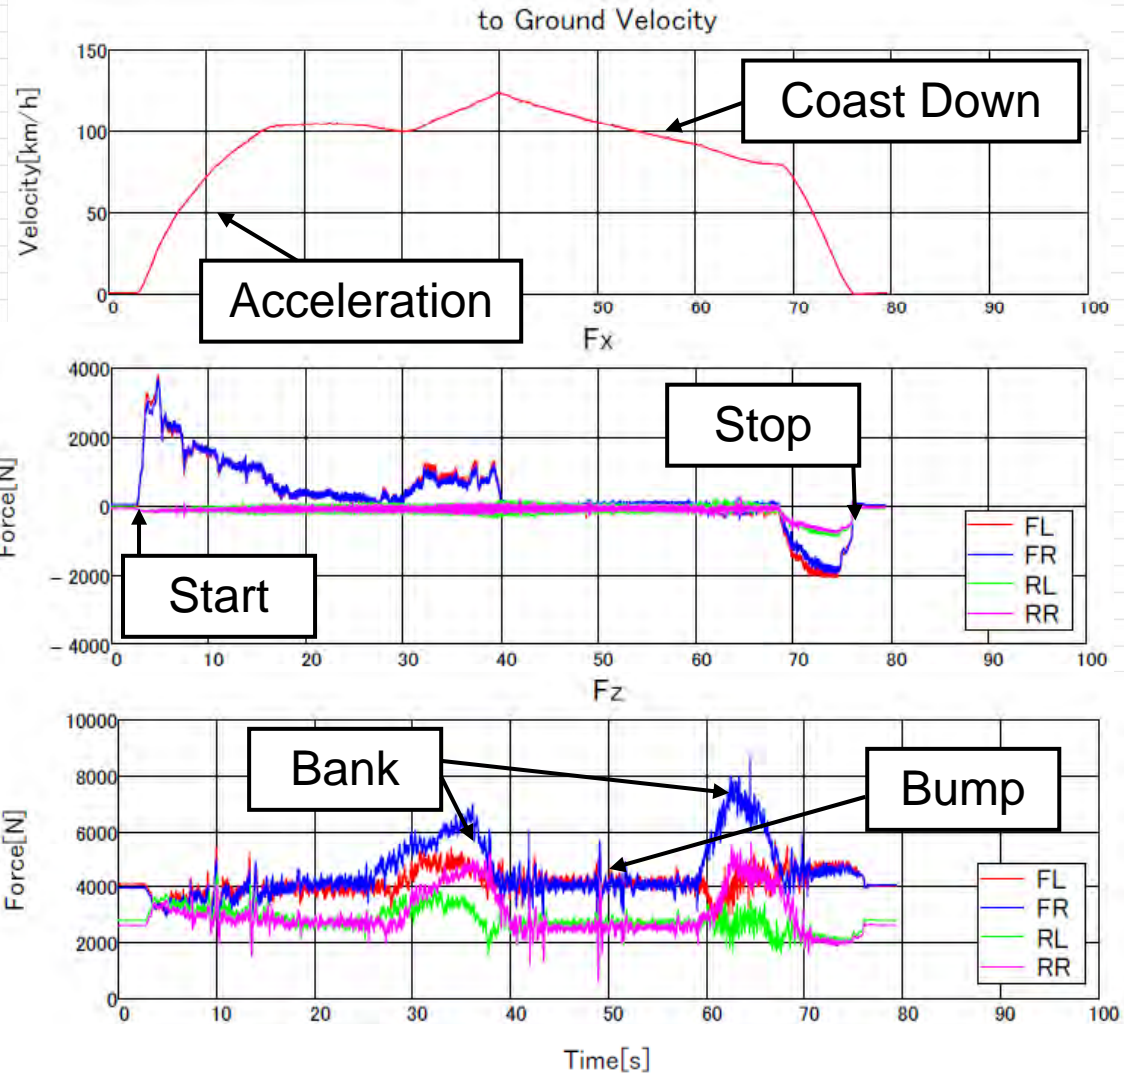

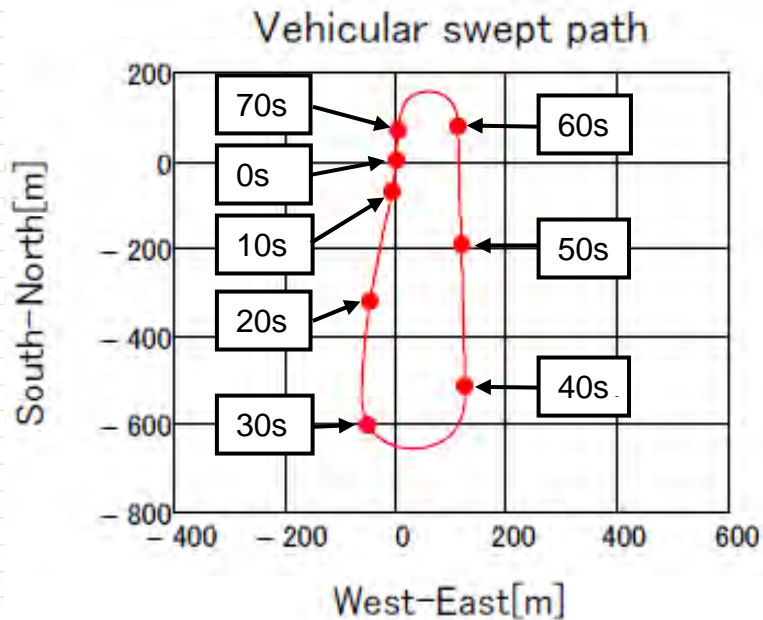

- Motivation
- Introduction of the used Measurement Equipment
- Introduction of the theoretical approach
- Description of the Test procedure
- **Results**
- Summary / Conclusions

Test Track Measurement Results

- Example plot of one round
- Fx shows mainly difference between front and rear wheel
- Fz shows change between left and right

Parameter Determination

Direct Measures from the sensor:

- Wheel torque M_y in Nm
- Tire longitudinal force F_x in N

Indirect Measures:

- Tire rolling inertia J_t in $\text{kg} \cdot \text{m}^2$
- Tire effective radius r_t in m
- Tire Angular acceleration $\dot{\omega}$ rad/s^2

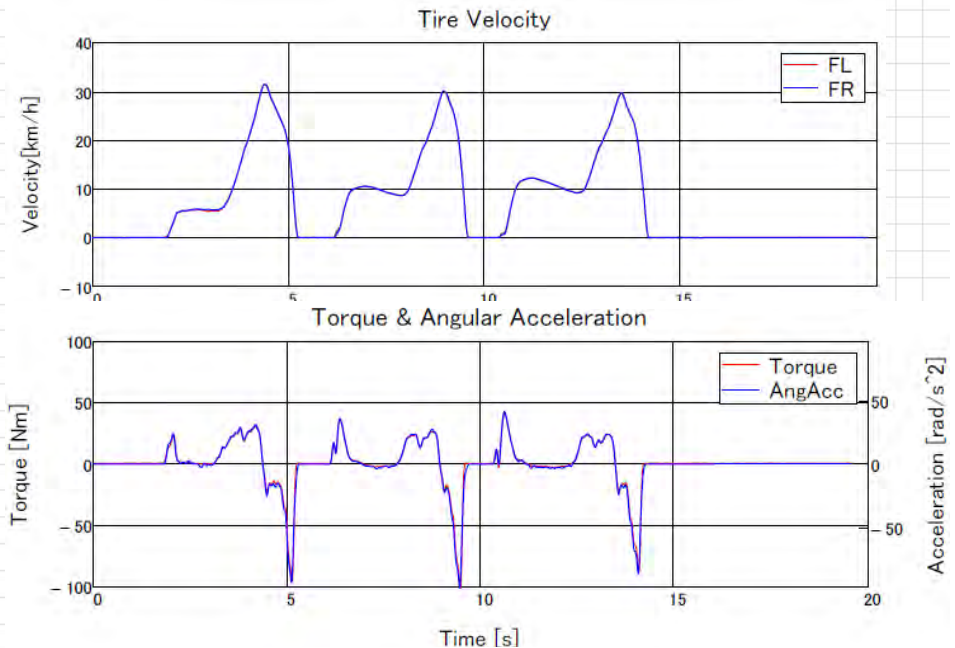

$$R_x = \frac{M_y + J_t * \dot{\omega}}{r_t} - F_x$$

Wheel inertia

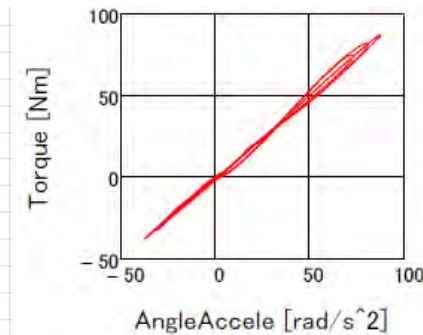

- Tire rolling inertia is premeasured using free load rotating wheel in acceleration and deceleration condition
- Measurement items
 - Tire angular speed ω [rad/s]
 - Angular acceleration $\dot{\omega}$ [rad/s²]
 - Wheel torque $M_{y_{free}}$ [Nm]
- Rolling inertia formula:

$$J_t = \frac{M_{y_{free}}}{\dot{\omega}}$$

Torque Vs. Angular acceleration

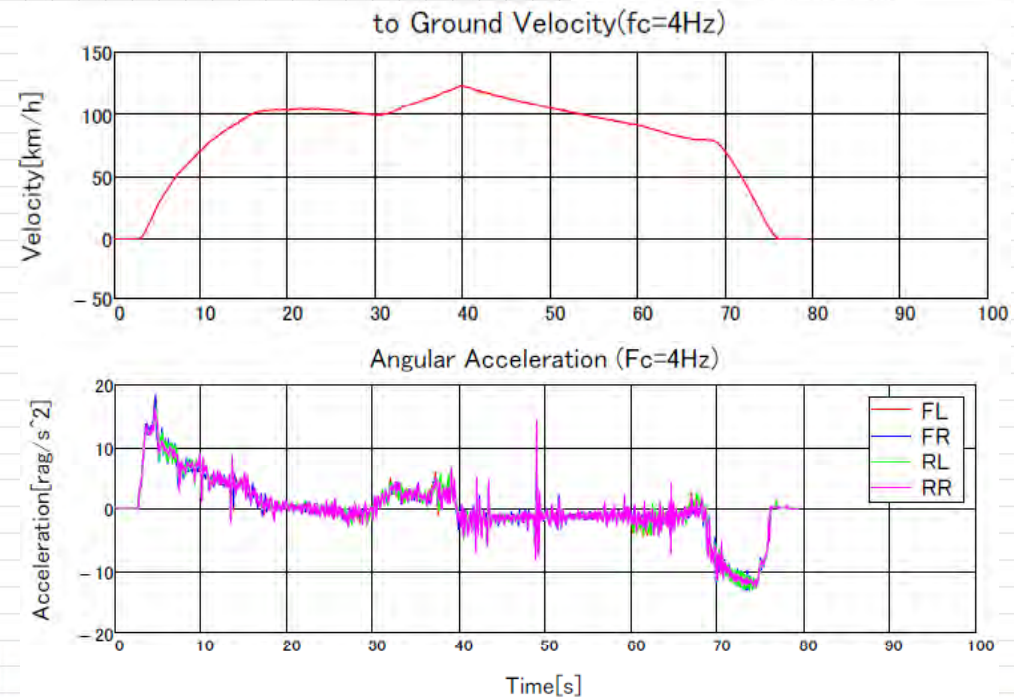

Angular acceleration determination

- Tire angular speed is measured from sensor angle encoder.
- Tire angular acceleration is calculated from angular speed signal by time derivative
- Measurement item:
 - Tire angular speed ω [rad/s]
 - Tire angular acceleration

$$\dot{\omega} = \frac{d\omega}{dt}$$

Tire radius determination

- Tire mean radius is calculated from vehicle velocity and tire angular speed.
- Vehicle velocity is measured from optical Doppler sensor
- Instant tire mean radius is measured.

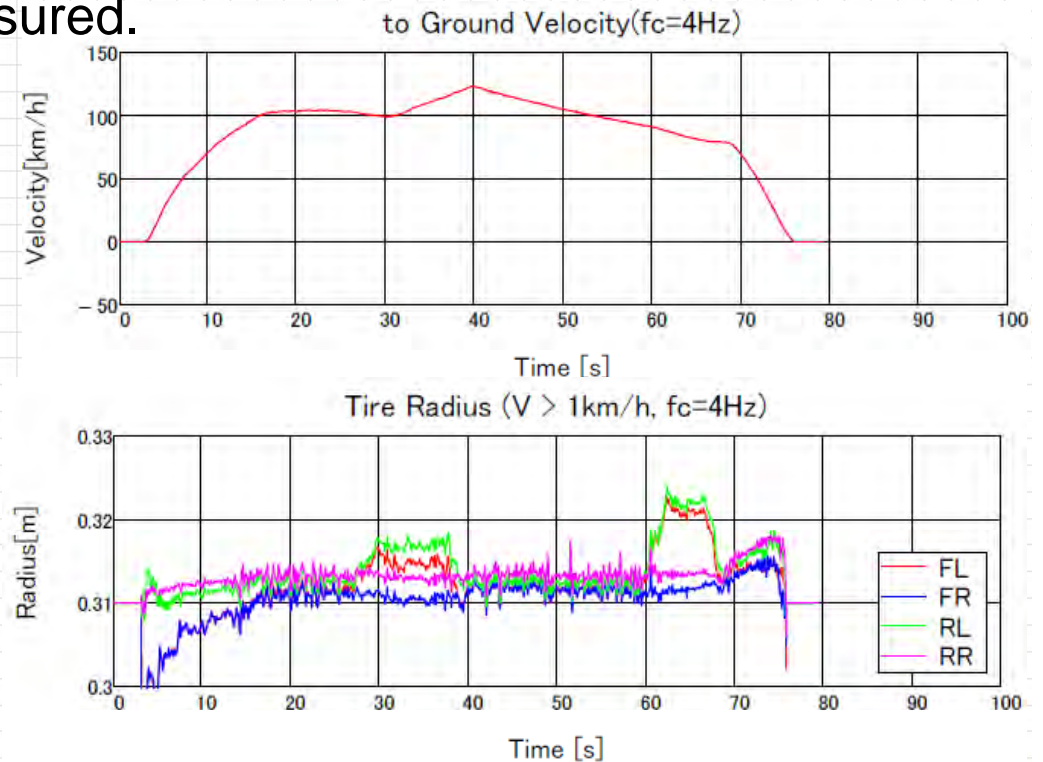

- Measurement items

- Vehicle velocity against road V_{ph} [m/s]

- Tire angular speed ω [rad/s]

- Tire radius formula
(Not considering tire slip)

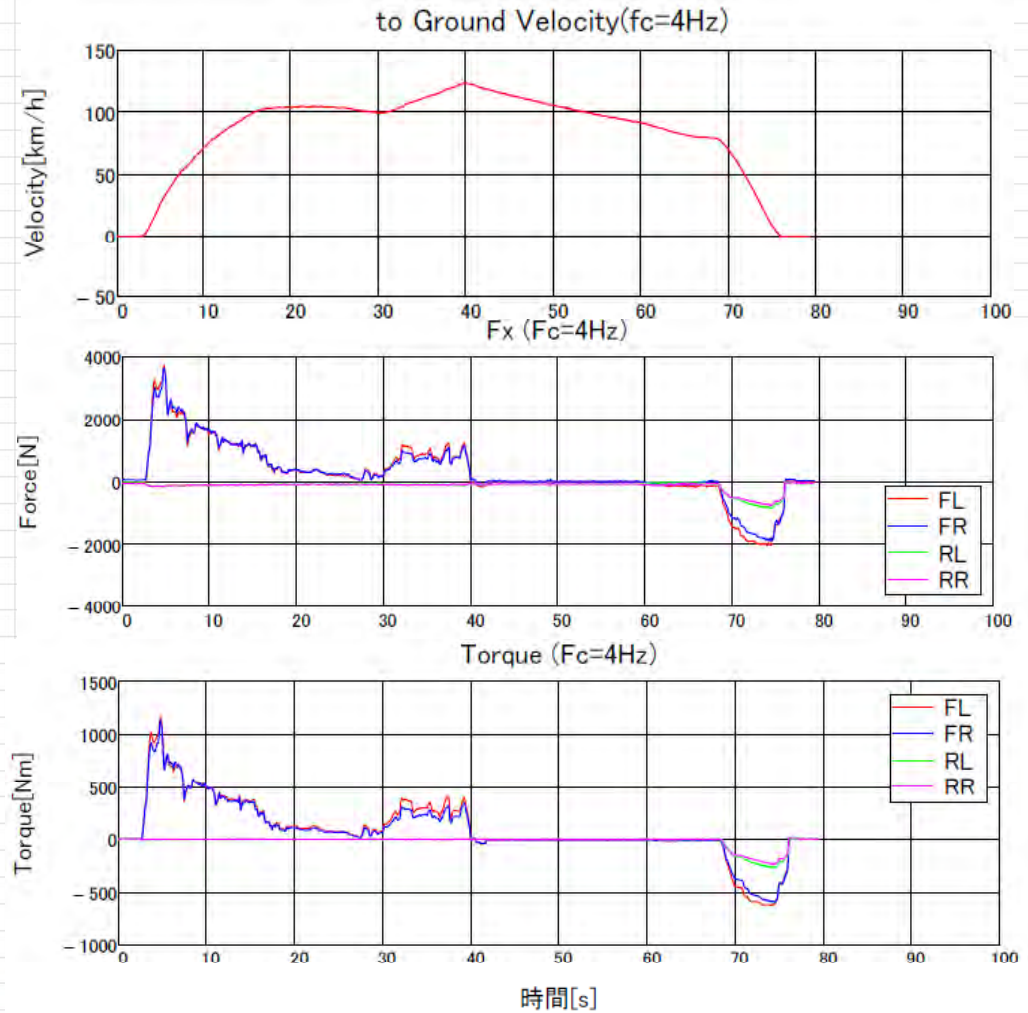

$$r_t = \frac{V_{ph}}{\omega} \quad [m]$$

Measurement parameter: Wheel torque and longitudinal force

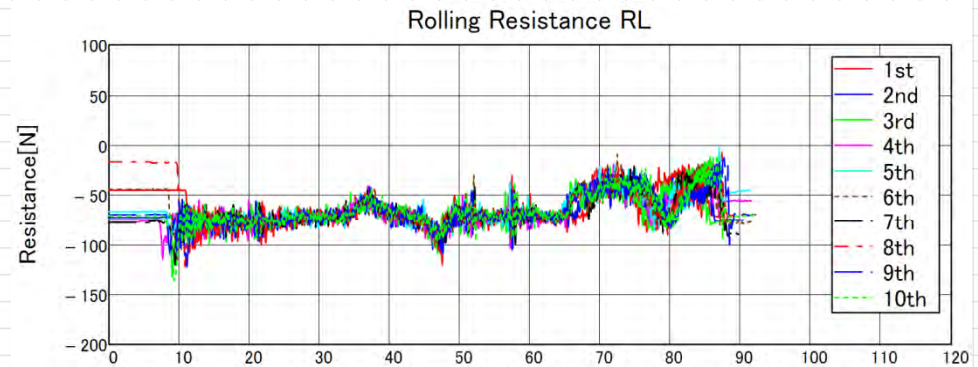

- Wheel torque M_y and longitudinal force F_x are measured from 6 components of the Wheel Force Sensor (WFS)

Rolling Resistance Results

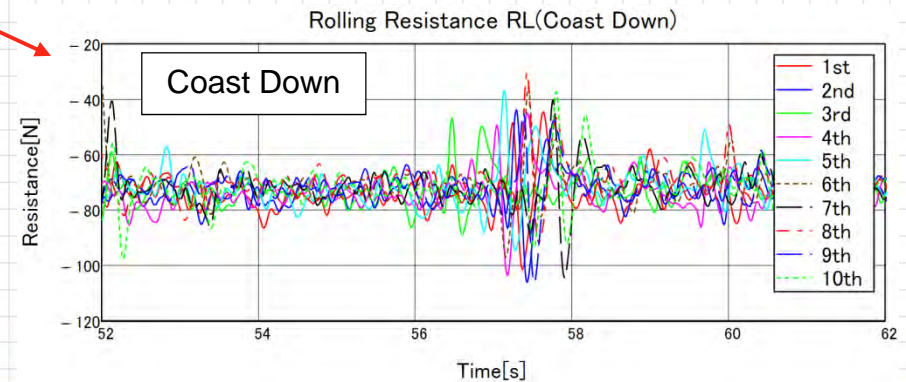

- To avoid tire slip error, driven wheel data is evaluated
- 10 laps of data
- To avoid some high frequency noise a low pass filter (4 Hz) is applied to the measurement data
- Very good repeatability for 10 laps

Rear Left Wheel results

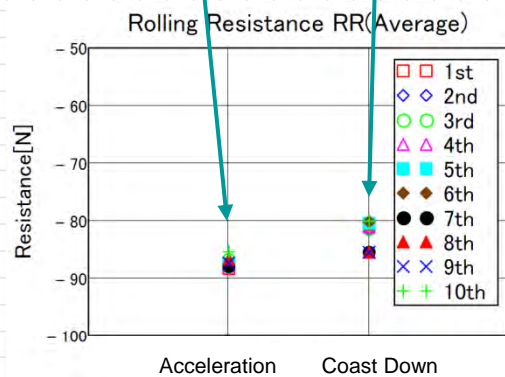

- Average Rx: $R_x = -76.1\text{N}$ (Acceleration), $R_x = -72.8\text{N}$ (Coast down)
- 10 laps data variation 3σ : 2.8N (Acceleration), 3.6N (Coast down)
- R_x for Acceleration and R_x for Coast down data are very close to each other: 3.3N

Rear Right Wheel results

- Average Rx: Rx = -87.6N (Acceleration). Rx = -82.6N (Coast down)
- 10 laps data variation 3σ : 2.5N (Acceleration), 6.6N (Coast down)
- Rx for Acceleration and Rx for Coast down data are very close to each other: 5.0N

Measurement result : Test rig

Test condition:

- Slip angle :0 [deg]
- Camber angle: 0 [deg]
- Wheel driven by steel belt
- Vertical load Fz: 1kN, 2kN, 5kN
- Static velocity: 5km/h, 10km/h, 20km/h, 60km/h, 80km/h, 120km/h
- Rolling resistance is directly measured from Fx using same sensor as on the road

Results:

- Rolling resistance is proportional to the vertical load and is not a function of velocity
- Rolling resistance at 2.7kN is 42N

Comparison: Real road vs Test rig

Real road rolling resistance :

- $R_x(\text{Left}) = 74 \text{ N}$
- $R_x(\text{Right}) = 82 \text{ N}$

Test rig:

- $R_x = 42 \text{ N}$

Reasons for the difference:

- Tire alignment on Road and rig is different
- Road surface condition
- Environment conditions
 - Wind force to tire
 - Temperature
- Measurement errors
 - Tire effective radius measurement

- Motivation
- Introduction of the used Measurement Equipment
- Introduction of the theoretical approach
- Description of the Test procedure
- Results
- **Summary / Conclusions**

Summary and Conclusion

Summary:

- A&D Sensor delivers high quality data
 - Repeatability of 10 lab data did show good match
- It was possible to measure the tire loss (rolling resistance) during real driving condition
- Great match on the results though 10 laps of data
- Rolling resistance measurement result is depending on driving conditions
 - We did observe difference between acceleration and coast down conditions
- There are differences between road and test rig results

Conclusion:

- WFS is a useful tool for analyzing energy loss at real driving condition
- We are very close to the dream and will continue this investigation

Thank you for your attention!
